

# WELCOME!

## NETWORK MODELING FOR EPIDEMICS

Martina Morris, Ph.D. University of Washington  
Steven M. Goodreau, Ph.D. University of Washington  
Samuel M. Jenness, Ph.D. Emory University

Development of methods, software, and learning materials presented throughout this course all supported by the **US National Institutes of Health**

# Objectives for the course

---

Understand the principles and methods of network analysis relevant to infectious disease epidemiology

- Descriptive network analysis
- Statistical network analysis with ERGMs and TERGMs
- Empirical study designs for networks

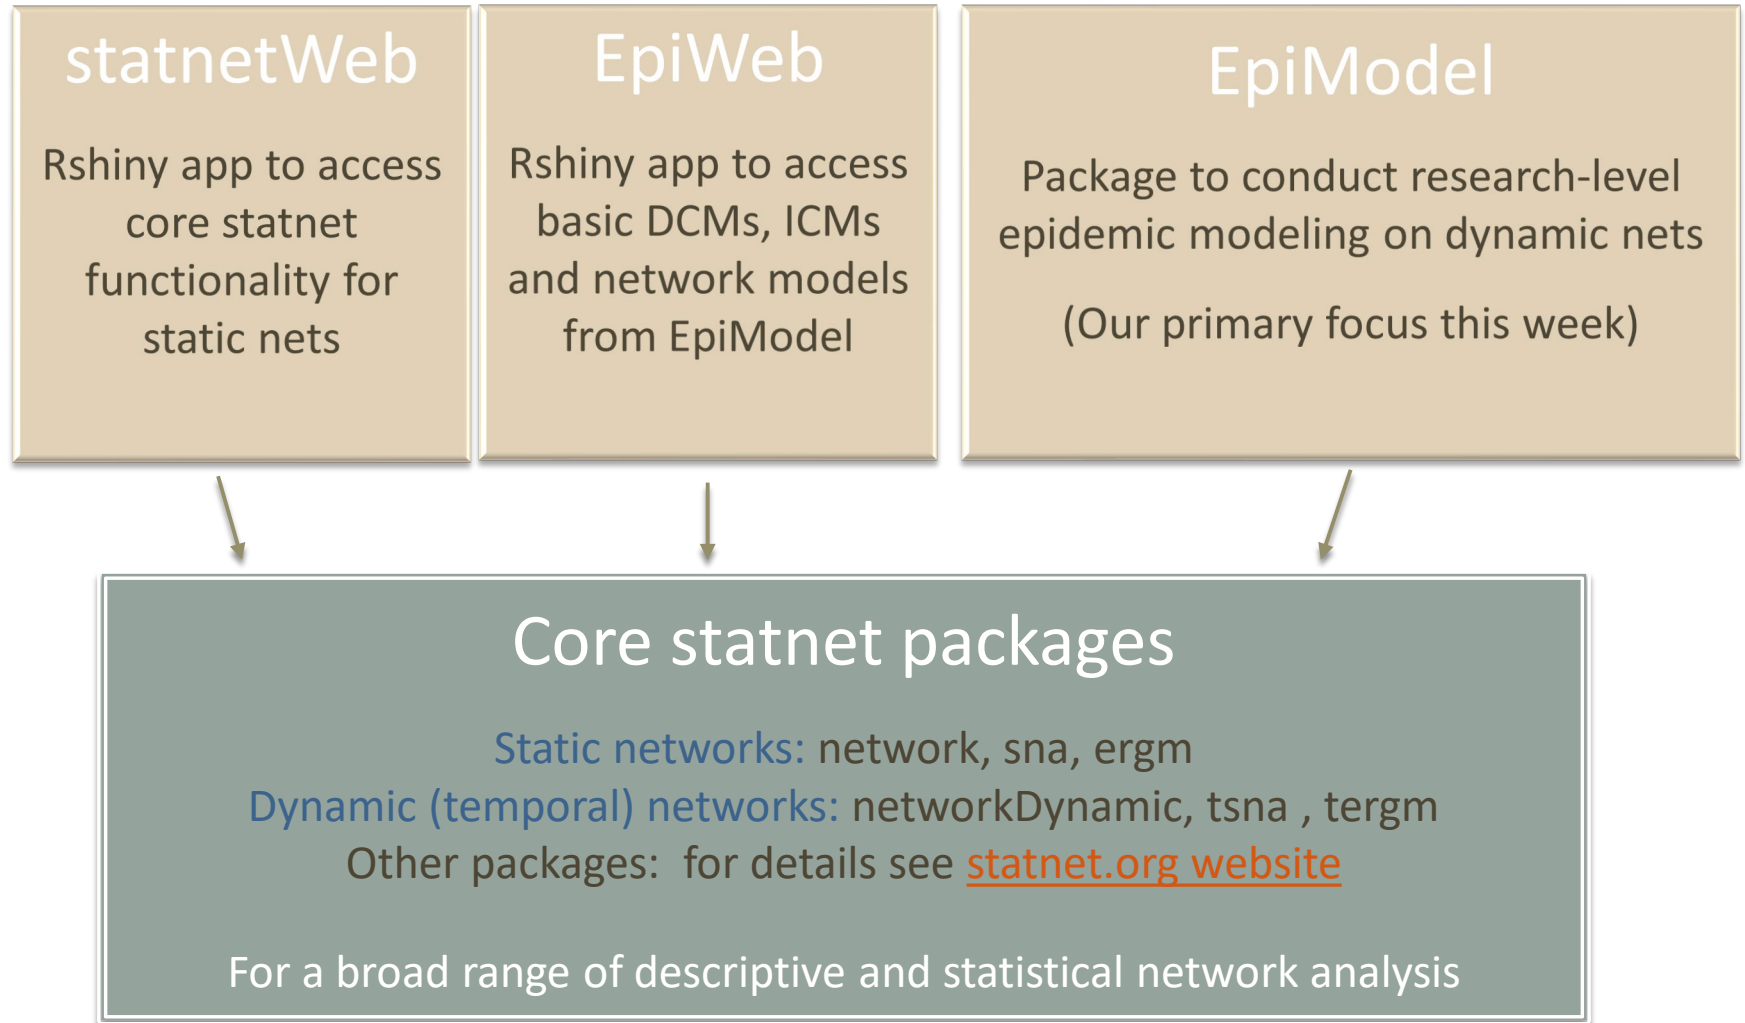

Develop the knowledge and software skills to run your own simple network transmission models, using **R** and the **EpiModel** package

Begin to learn how to extend **EpiModel** code for your own research applications

# Lesson plan

Day	Module	Content
W	1	Intro, terms & concepts
	2	Statistical models for networks: theory
T	3	Statistical models for networks: practice
	4	Basic EpiModel in closed populations
	5	EpiModel: working with nodal attributes
	6	Data and network model parameterization
F	7	EpiModel in open populations (demography) pt. 1
	8	EpiModel in open populations (demography) pt. 2; visualization
	9	Extending EpiModel
	10	Discussion of projects; next steps; future resources

# Software (all based in R)

# Show of hands - who has experience:

- With epidemic modeling?
  - Using compartmental models? \*
  - Using stochastic agent-based models? \*
  - Using (full-fledged) network models? \*
  - Using EpiModel?

What do we mean by these terms? We'll elaborate in a bit. For now just give your best answer.

# Show of hands - who has experience:

- With R?
- With social network analysis?
  - Using descriptive methods?
  - Using statistical inference methods?
  - For static networks?
  - For dynamic networks?
  - Using the statnet suite of packages?

# Whose research interests relate to:

- Human pathogens?
  - HIV?
  - Other sexually transmitted infection(s)?
  - Respiratory /airborne pathogen(s)?
  - Vector-borne pathogen(s)? (mosquitos, etc.)
  - Some other human pathogen?
- Animal pathogens?
- Diffusion of an intervention/behavior/information?
- Diffusion of something else entirely?

# Background to epidemic modeling (1)

## A lightning- fast overview

All\* models, regardless of type, will contain the following ideas:

1. **Time** as a dimension over which the model unfolds
2. At least one type of **element** (aka **agent**; e.g. human beings)...
  - ... of which there is a **population**...
  - ... whose members are capable of being “**infected**”...
  - ... and also capable of **infecting** others
3. At least one **entity** capable of doing the “**infecting**” (e.g. SARS-CoV2)
4. Some type of **contact process** by which the infection occurs
5. A **record** of whether and when the elements are infected

*\* pretty much; there are always weird exceptions to every rule*

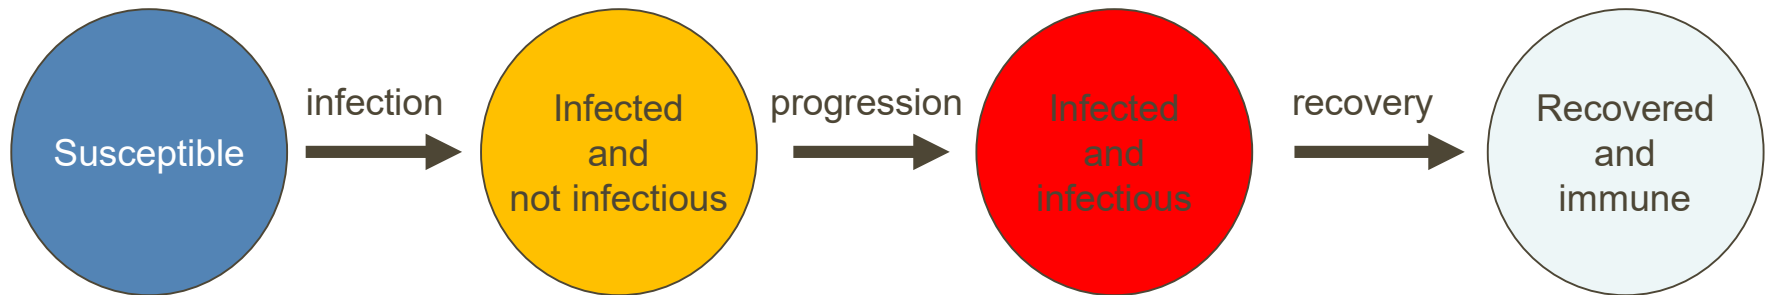

# Background to epidemic modeling (2)

## A lightning- fast overview

Some models have additional infection statuses, e.g.

- recovered and immune
- infected but not yet infectious
- perhaps stages with different levels of infectiousness

# Background to epidemic modeling (3)

## A lightning- fast overview

Most but the very simplest of toy models will have:

1. Attributes of the elements (other than infection status), e.g.
  - demographic (sex, age....)
  - behavioral (level of sociality; occupation....)
  - clinical (tested or not; on treatment or not...)
  - geospatial (community; coordinates....)
2. Processes by which at least some of those attributes can change

Many consider attributes for the infectious agent as well, e.g.

- strain
- presence of specific mutations

# Background to epidemic modeling (4)

## A lightning- fast overview

Fundamental summary measure:  $R_0$

Captures the epidemic “persistence threshold” and velocity of transmission

*Definition:* The expected number of secondary infections generated by the first infected case in a population of susceptibles

Value of $R_0$	Implication
< 1	The first infected individual will on average infect < 1 person total. Transmission is too low for epidemic persistence
> 1	The first infected individual will on average infect >1 person total. Epidemic will typically grow and persist
= 1	Right on the threshold between persistence and extinction. Epidemic will typically just putter along

# Deterministic compartmental modeling (DCMs)

## A lightning- fast overview

- Only the aggregate count in each state (“compartment”) is represented, not individual persons
  - $S(t)$  = # susceptible, etc.
  - Within each compartment, units are homogeneous
- Transitions (“flows”) represent the aggregate count that moves from one compartment to another at any time point
  - Flows are represented by differential equations (or difference equations if in discrete time)

# Deterministic compartmental modeling (DCMs)

## A lightning- fast overview

Change in # of susceptible persons per time unit

$$\frac{dS}{dt} = -\beta SI/N$$

Change in # of infected persons per time unit

$$\frac{dI}{dt} = \beta SI/N - \rho I$$

Change in # of recovered persons per time unit

$$\frac{dR}{dt} = \rho I$$

- $\beta$  and  $\rho$  are model parameters

- Q: Where are the contact events?

- A: embedded in the infection flow

# Deterministic compartmental modeling (DCMs)

## A lightning- fast overview

Common notation for infections

$$\beta SI/N$$

where  $\beta$  is called the “force of infection”

Can be disaggregated as:

$$\tau c SI/N$$

where  $c$  = “contact rate”  
 $\tau$  = “transm. prob”

So:  $S$  susceptibles each have  $c$  contacts per unit time

$I/N$  of the contacts are with infected

each susceptible-infected contact has probability  $\tau$  of transmitting

# Deterministic compartmental models

- Compartmental models are usually deterministic – each run gives the same result
- Measures = **predicted** counts (and represent the means of an equivalent stochastic process over an infinite number of runs)
- Compartments and flows can represent fractional persons

# DCM weaknesses

- Do not show the stochastic variation in a system
  - Stochastic CMs do exist, but only solve this one weakness
- Adding heterogeneity blows up quickly
  - Requires new compartments
    - e.g. adding 2 sexes means going from 3 compartments to 6: SF, IF, RF, SM, IM, RM
    - What if we wanted to add in 4 racial/ethnic groups? 5 ages? 5 categories of viral load? Testing? Treatment? Circumcision? Etc.
  - And if heterogeneity isn't in discrete categories?

# DCM weaknesses

- Representing complex partnership network patterns is hard (or impossible, depending who you ask)
  - Non-random mixing on an attribute can be added into the incidence term easily enough
    - Raises additional questions in open populations where group sizes can change
  - But other partnership patterns are harder
    - Like a tendency to only have one partner at a time?
    - To be more (or less) less likely to have contact with your partner's partner?
    - Remember that compartments only considered people in the aggregate; individuals are not uniquely identified
- And there is no general method for jointly estimating the parameters of a system of partnerships like this

# Individual-based models

- Represent each individual member of the population explicitly
- This might take the form of a data frame (in R speak)
  - Each row is an individual
  - Each column is an attribute
- Use code instead of equations to represent the relevant dynamic processes

# IBM pseudocode

```
# Initial conditions
  # create a data.frame (nrow = # of agents, ncols = # of attributes)
  # assign infection status (S, I, R) as one attribute
  # assign all other attributes
# Simulate epidemic
for (at = 1:num.timesteps) {
  # infection
    # draw the number of contacts for that step
    # draw 1 pair of agents for each contact
    # filter to just the discordant SI pairs
    # flip coin for each pair to determine if transmission
    # do bookkeeping for new infections
  # recovery
    # identify infected elements
    # flip coin for each case to determine recovery
    # do bookkeeping for recoveries
  # update other attributes
    # exact code depends on the nature of the attribute
}
# process output
```

these can  
be made  
to depend  
on the  
attributes  
of the  
agents

# IBM strengths

- Show the stochastic variability in these systems
- Can handle multiple forms of heterogeneity with relative ease
  - With individuals identified, they just get labeled
- Simple models have some simple closed form solutions for  $R_0$ 
  - For examples, see [this article](#)

# IBM weaknesses

- Representing heterogeneity *in the contact process* that creates the partnership network is still hard
  - Some example include queuing processes and “stub matching”
  - But these are not very realistic representations
- And here, too, there is no general method for jointly estimating the parameters of this complex process from data.

# Final note on terminology

- Contacts vs. acts: a key distinction
  - E.g. think of sexual activity - when we say “# of contacts per year”
    - Does it mean number of sex acts?
    - Or numbers of different partners?
- From here on out, we will use the terms “acts” and “partners”
- This distinction matters for disease dynamics when there are repeated acts with the same person
